• Laplacian eigenfunctions and neural networks... This detailed example demonstrates how one can use quaternions to represent and execute rotations elegantly in 3D space. Further, the example shows that a quaternion-based optimization approach for performing rotation of an orthonormal 3D basis to optimally approximate a given non-orthogonal set of normalized vectors is effective and computationally efficient; the determination of the approximation-error-minimizing optimal rotation angle is defined by a univariate function minimization. Unfortunately, the generalization of quaternions to higher-dimensional spaces is complicated and is subject to ongoing research in algebra, geometric algebra and mathematical physics. Generally, the resulting "number systems" lose properties with increasing dimension (loss of commutative and associative

• Note. The 16x16 multiplication table for sedenions includes the 2x2, 4x4 and 8x8 multiplication tables for complex numbers, quaternions and octonions as "sub-tables" in the upper-left corner, as indicated. More recently, octonions and sedenions have gained significant interest in STRING theory.

Stratovan■ OBJECT AND MATERIAL EIGENFUNCTIONS - Cont'd.

• Laplacian eigenfunctions and neural networks:... • Note. Octonions can be used

to represent rotations in an 8-dimensional space. Since octonion multiplication is not associative, calculations become more complicated. While this topic is interesting, its discussion goes beyond the scope of these notes.

The literature covering octonions ("Cayley numbers"), Cayley algebra and Clifford algebra provides details.

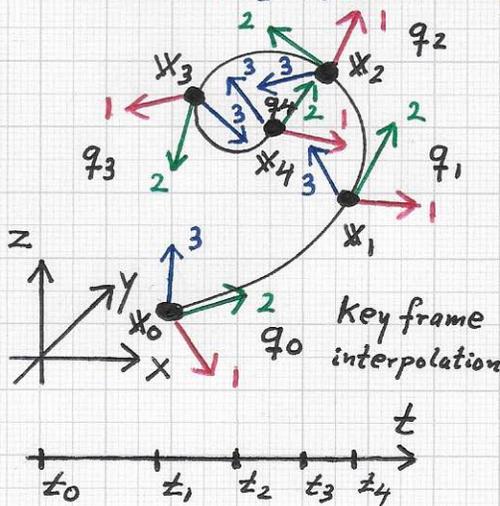

---

It turns out that quaternions have also become relevant for computational neural network problems and applications. Quaternions gained substantial interest in computer graphics, especially computer animation, since they provide an elegant and computationally efficient and (in some sense) numerically stable tool for performing "smooth rotations." While computer animation employs quaternions to represent and perform rotations as part of "designing" an object's or character's movements, quaternions can also be used for designing features/characteristics of objects in images, videos or 3D volumetric scans. Thus, quaternions are briefly reviewed at this point with a focus on their use in animation and data analysis (for object description and recognition).

...

OBJECT AND MATERIAL EIGENFUNCTIONS - Cont'd.

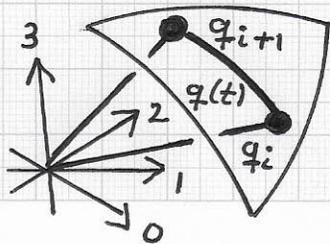

• Laplacian eigenfunctions and neural networks: Defining and smoothly interpolating "key frames" is crucially important in computer animation. More precisely, one must typically specify an object's position and orientation for parameter values (time points)  $t_0, \dots, t_n$  and subsequently interpolate the specified data — defining the desired spline over the interval  $[t_0, t_n]$  that can subsequently be evaluated at the necessary time discretization / sampling for actual rendering.

The left figure illustrates the basic problem: Given are time points  $t_0, \dots, t_4$  with associated positions  $x_0, \dots, x_4$  in 3D space and corresponding orientations — called  $q_0, \dots, q_4$  in the figure

The goal is the computation of an interpolant that de-

finies a smoothly interpolated position  $x(t)$  with orientation  $q(t)$  for  $t \in [t_0, t_4]$ . This interpolant is constructed in "4D quaternion space."

The left figure shows the two unit quaternions  $q_i$  and  $q_{i+1}$  — resulting by mapping two keyframe rotation / orientation matrices to  $q_i$  and  $q_{i+1}$  —

to be interpolated by  $q(t)$  that lies on the unit 4D hypersphere.

Stratoran■ OBJECT AND MATERIAL EIGENFUNCTIONS - Cont'd.

- Laplacian eigenfunctions and neural networks:... Thus, instead of interpolating the specified keyframe rotation matrices in 3D space, the matrices are mapped to their "unit quaternion representation equivalents"; one can then compute an interpolating "quaternion curve" in 4D space, subject to satisfying that the final interpolating "quaternion curve"  $q(t)$  consists only of unit quaternions that properly represent a rotation matrix for 3D space, for every  $t \in [t_0, t_n]$ . One can consider a multitude of interpolation methods for the construction of a continuous and smooth curve  $q(t)$ . (For example, the paper "U-Quaternion Splines for the Smooth Interpolation of Orientations" by Gregory M. Nielson, IEEE Trans. on Visualization and Computer Graphics 10(2), 2004, pp. 224-229, describes an elegant scheme based on the concepts of B-splines and cubic splines using a tension parameter ( $u$ .) One might also consider the use of an interpolation method that first interpolates the quaternions  $q_0, \dots, q_n$  smoothly via a curve  $q(t)$  that is not forced to lie on the unit 4D hyper-sphere (not forced to define exclusively unit quaternions  $q(t)$  for all  $t$ -values). A resulting  $q(t)$  curve point can be normalized in a subsequent step, thereby ensuring that  $q(t)/\|q(t)\|$  defines a proper rotation matrix.
