1. (90) The CUDA code below solves a problem similar to the root finding example in Section 4.11. It finds the root of a user-supplied function  $f()$ , which is increasing on  $(0,1)$  and has a root somewhere inside. The initial search interval is  $(0,1)$ , but the interval gets smaller with each iteration. At any iteration, the current interval is divided in subintervals, with each thread handling one subinterval. Fill in the blanks.

```
#include <stdlib.h>
#include <stdio.h>
#include <cuda.h>

// f() defined on (0,1), strictly increasing,
// with a root somewhere inside

__device__ float f(float x) {
    return x*x - 0.5;
}

#define BLOCKSIZE 192

__global__ void check1tile(float *devab)
{
    int threadnum =
        blockIdx.x * BLOCKSIZE + threadIdx.x,
    totthreads = gridDim.x * BLOCKSIZE;
    float a = devab[0];
    float b = devab[1];
    float xinc = (b-a) / -----; // blank (a)
    float x = -----; // blank (b)
    if (f(x) < 0)
        if (f(x+xinc) > 0) {
            -----; // blank (c)
            -----; // blank (d)
        }
    }

int main(int argc, char **argv)
{   int i;
    float hosab[2] = {0.0,1.0},
          *devab;
    int niters = atoi(argv[1]);
    int nblocks = atoi(argv[2]);
    int float2 = 2 * sizeof(float);
    cudaMalloc((void **)&devab, float2);
    -----; // blank (e)
    for (i = 0; i < niters; i++) {
        dim3 dimGrid(nblocks,1);
        dim3 dimBlock(BLOCKSIZE,1,1);
        check1tile<<<dimGrid, dimBlock>>>(devab);
        -----; // blank (f)
    }
    -----; // blank (g)
    for (int i = 0; i < 2; i++)
        printf("%f\n", hosab[i]);
    cudaFree(devab);
}
```

2. (10) As a measure of thread divergence, we might consider *utilization*, meaning the proportion of time threads are actively executing an instruction.

As a toy example, say we have 2 blocks of 4 threads

each, executing 10 instruction cycles. That's a possible 80 instruction executions. But suppose 1 of the threads is idle during 6 cycles and another is idle during 15 cycles. Then our utilization would be  $(80 - 6 - 15)/80$  or about 86%.

Consider the code in Problem 1, slightly modified:

```
s = f(x); t = f(x+xinc);
if (s < 0)
    if (t > 0) {
        -----; // blank (c)
        -----; // blank (d)
    }
```

Suppose for simplicity that each of the 4 lines starting with the first **if** compiles to one machine instruction. With the specific  $f()$  used above, find the approximate utilization for those 4 instructions during the first iteration. **Your answer must be an R expression.** Note: Your answer should not depend on the number of threads.

## Solutions:

```

#include <stdlib.h>
#include <stdio.h>
#include <cuda.h>

// f() defined on (0,1), strictly increasing,
// with a root somewhere inside

__device__ float f(float x) {
    return x*x - 0.5;
}

#define BLOCKSIZE 192

__global__ void check1tile(float *devab)
{
    int threadnum = blockIdx.x * BLOCKSIZE + threadIdx.x,
        totthreads = gridDim.x * BLOCKSIZE;
    float a = devab[0];
    float b = devab[1];
    float xinc = (b-a) / totthreads;
    float x = a + threadnum * xinc;
    if (f(x) < 0)
        if (f(x+xinc) > 0) {
            devab[0] = x;
            devab[1] = x + xinc;
        }
}

int main(int argc, char **argv)
{
    int i;
    float hosab[2] = {0.0,1.0},
        *devab;
    int niters = atoi(argv[1]);
    int nblocks = atoi(argv[2]);
    int float2 = 2 * sizeof(float);
    cudaMalloc((void **)&devab, float2);
    cudaMemcpy(devab, hosab, float2, cudaMemcpyHostToDevice);
    for (i = 0; i < niters; i++) {
        dim3 dimGrid(nblocks,1);
        dim3 dimBlock(BLOCKSIZE,1,1);
        check1tile<<<dimGrid,dimBlock>>>(devab);
        cudaThreadSynchronize();
    }
    cudaMemcpy(hosab, devab, float2, cudaMemcpyDeviceToHost);
    for (int i = 0; i < 2; i++) printf("%f\n",hosab[i]);
    cudaFree(devab);
}

```

2. All threads will execute the first **if**. The threads having a subinterval to the left of  $\sqrt{0.5}$  will also execute the second **if**. With  $n$  threads, that means that there will be about  $n + 2 \times \sqrt{0.5} \times n$  instructions executions during  $4n$  opportunities, for a utilization of  $(1+2*\sqrt{0.5})/4$ .
